# Theoretical background for the search for scalar leptoquarks

---

This chapter describes theoretical foundations required for the search for scalar leptoquarks including the successful Standard Model of elementary particle physics evolved from the symbiosis of experimental achievements and theoretical milestones. Besides its success some issues still remain unsolved and could be a hint to physics beyond the Standard Model, giving space to introduce the Leptoquark Model as one possible extension.

## 3.1 The Standard Model of particle physics

A remarkable development for understanding nature is the Standard Model of particle physics, embracing physics at the most fundamental level. This quantum field theory, incorporating the conceptual frameworks of special relativity and quantum mechanics, describes the constituents of matter and the laws governing their interactions. [1] Despite its success of being the most promising theory so far capable of explaining the observed results within its domain in agreement with empirical data, it seems not to be the complete story. [2]

One of the most important concept in physics is that of symmetries, because they are deeply connected with conservation of laws, following Noether's Theorem. A physical property responds to a symmetry transformation in two different ways. It can appear in form of an invariant under symmetry transformation, leaving that property unchanged, or as covariant, changing their property induced by the symmetry transformation. Fundamental symmetries of particle physics include space

group	defining property	application
$U(n)$	$n \times n$ unitary ( $U^\dagger U = 1$ )	$U(1)$ electromagnetism
$SU(n)$	$n \times n$ unitary ( $U^\dagger U = 1$ )	$SU(2)$ weak interactions
	with $\det U = 1$	$SU(3)$ strong interactions
$SO(n)$	$n \times n$ orthogonal ( $O^\top O = 1$ )	$SO(3)$ rotations
	with $\det O = 1$	$SO(3, 1)$ Lorentz transformations

**Table 3.1:** Lie symmetry groups for the gauge interactions of the Standard Model [1].

translation symmetry and hence the conservation of momentum, rotational invariance and hence conservation of angular momentum and time translation invariance leading to energy conservation. The formal mathematical description for fundamental symmetries is based on group theory. In case of particle physics almost all groups are Lie groups  $\mathcal{G}$ , that are a set of objects  $\{g_i\}$ , which can be combined with a binary operation and has four basic properties: closure, identity, inverse element and associativity. Additionally, the group elements are continuous and differentiable functions of some finite set of parameters  $\theta_a$ :

$$g = g(\theta_1, \dots, \theta_N) = \exp[i\theta_a \mathbf{T}^a] = \exp[i\vec{\theta} \vec{\mathbf{T}}] \quad \text{with } a = 1, \dots, N \quad (3.1)$$

Here  $\mathbf{T}^a$  are the generators of the group from which all elements of the group can be created. The irreducible representatives of a group can be written as complex matrices\*, acting on the wave function of the particles and on charges as well as on space-time coordinates. [1] The local symmetry  $SU(3)_c \times SU(2)_L \times U(1)_Y$  summarizes the gauge interactions of the Standard Model (see table 3.1). Here  $c$  indicates the strong force,  $L$  the left handed chirality of the weak regime and  $Y = B + s$  the hypercharge calculated from baryon number  $B$  and strangeness  $s$ . [3] Besides the continuous symmetries above also important discrete symmetries exist in the Standard Model like parity  $P$ , referring to the transformation  $\vec{x} \rightarrow -\vec{x}$ , time reversal  $T$ , referring to  $t \rightarrow -t$ , and charge conjugation  $C$ , corresponding to the exchange of a

---

\*Irreducible means that not all representing matrices of the group can be decomposed into block-diagonal form simultaneously [1].

particle with its anti-particle. The weak force breaks  $P$  and  $C$ , but not the product of  $CPT$ . [2]

Matter and its interactions can be described by two basic types of particles and four fundamental forces, i.e. the electromagnetic force, the weak and the strong force and gravity. Fermionic particles, following Fermi-Dirac statistics, make up matter, whereas bosons, following Bose-Einstein statistics, are acting as mediators of the fundamental forces. [4][5]

The fermions can be further categorized into 6 leptons  $l$  characterized through the lepton quantum number  $L_l$  and 6 quarks  $q$  characterized through the baryon quantum number  $B$  together with their anti-particles ( $\bar{l}$  respectively  $\bar{q}$ ). The only difference between particle and anti-particle is contrary electrical charge and contrary lepton and baryon number respectively. Leptons occur in three generations with different flavour – electron (e), muon ( $\mu$ ) and tauon ( $\tau$ ) – and can carry electrical charge  $Q = \pm e$  in units of the elementary charge. The electrically neutral leptons are the neutrinos  $\nu_l$ . [5]

Table 3.2 shows the leptons with selected properties.

The quarks also occur in three generations and carry electrical charge of either  $Q = \pm \frac{1}{3}e$  or  $Q = \pm \frac{2}{3}e$  in units of the elementary charge as well as color charge. Possible color charges are red, green and blue and the additional anti-colors indicate that quarks are interacting with the strong force among the electromagnetic and weak interaction. [5] Quarks only occur confined in color-neutral compound systems called hadrons. Baryons are three-quark hadronic states with baryon number 1 and mesons are quark-anti-quark hadronic states, having a baryon number of 0. [4] The reason for quark confinement can be found in the potential  $V(r)$  between quarks and anti-quarks depending on distance  $r$ . The potential has the shape  $V(r) \propto \frac{-1}{r} + \text{const} \cdot r$ . When separating a quark-anti-quark pair, additional potential energy must be supplied, which can exceed the potential  $V(R) > 2m_q$  for more than two quark masses at distance  $R$ . Quantum fluctuations result in the origin of a new quark pair in between. The final state now consists of two pairs, again externally color-neutral. [2] Table 3.2 shows the different quark flavors up, down, charm, strange, top and bottom with some characteristic properties.

The bosons shown in table 3.2 are the quanta of the fundamental forces [4]:

- The photon  $\gamma$  is the mediator of the electromagnetic force.
- Three mediators  $Z^0$ ,  $W^+$  and  $W^-$  for the weak force.

### 3 Theoretical background for the search for scalar leptoquarks

**Table 3.2:** Overview of leptons  $l$ , quarks  $q$  and gauge bosons as mediators of the fundamental forces with some selected properties and quantum numbers like electrical charge  $Q$ , mass  $m$ , lepton number  $L_l$  and baryon number  $B$ . [2][6]. The fermion anti-particles are not shown due to the only difference in opposite electrical charge and lepton/baryon number.

- 8 colored gluons as mediators for the strong force.
- The Higgs boson  $H^0$  as quantum of the Higgs field, providing the masses for the elementary particles.

At the current state of research a quantum field theory of gravity is purely hypothetical. The mediator for such theory would be the graviton (see chapter 3.2). A second aspect is that on elementary particle scales gravity is insignificant compared<sup>†</sup> to all other forces and is therefore not originally considered in the Standard Model. [4]

**Figure 3.1:** The Standard Model with its fermions and bosons and the involved interactions. The solid blue line indicates which particles interact with each other. Loops depict self-interaction. [7]

Figure 3.1 summarizes the picture of the Standard Model with its fermions and bosons. The lines indicate which particles interact with each other through the mediators, including self-interaction.

---

<sup>†</sup>Relative strength of gravity compared to the weak interaction is  $10^{-35}$  [1].

## 3.2 Beyond the scope of the Standard Model

Nevertheless there are still many puzzles left which are not described by the Standard Model. That circumstance keeps physicists well motivated to gain further progress and to push the frontiers of our understanding. [2]

**Neutrino masses** are confirmed by various neutrino oscillation experiments [8][9], although the Standard Model does not predict neutrino masses. The neutrino flavor states  $\nu_\alpha$  with  $\alpha = e, \mu, \tau$  are quantum entangled with the mass states  $\nu_i$  where  $i = 1, 2, 3$  described by an unitary matrix  $U_{\alpha i}$  [10]. One possible extension of the Standard Model, explaining neutrino masses, is the seesaw mechanism. Because of the absence of the right chirality spinor components  $\Psi_{R,j}$ , the mass term of the Dirac lagrangian  $\bar{\Psi}_L \Psi_R + \bar{\Psi}_R \Psi_L$  cannot be formed in case of neutrinos. One possible solution is to describe the neutrino masses with a Majorana mass term, which introduces very massive\* right-chiral neutrinos besides light weight left-chiral neutrinos. One caveat is that such right-chiral neutrinos then have to exist, although within the Standard Model there are only left-handed neutrinos known. [2]

**Quantum gravity** could be the embedding of general relativity into a framework of quantum theory. Quantum theory provides a well confirmed framework for all theories describing particular interactions. Therefore it would be appealing to have a quantum formulation of gravity, following the example of all other fundamental forces and being one step closer to an unified description. From the view point of cosmology, quantum gravity could be an encompassing theory for a more fundamental understanding where general relativity breaks down, when it comes to the initial conditions of the early universe or conditions of black holes. [11]

## 3.3 Leptoquark Models

---

\*So massive that it is beyond today's observable mass limit [2].

---

# Experimental setup for the search for scalar leptoquarks

---

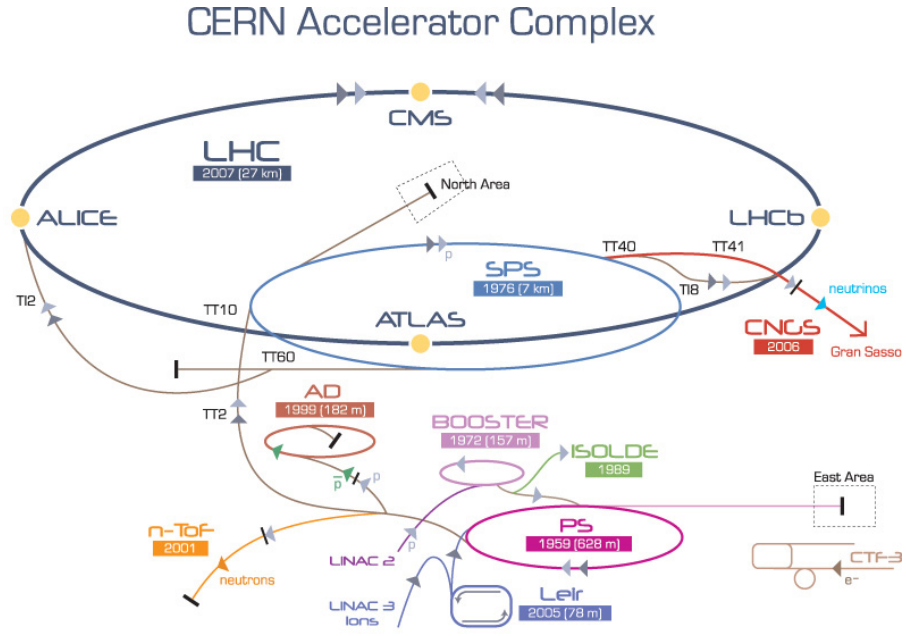

For the search for scalar leptoquarks the ATLAS detector at the Large Hadron Collider (LHC) is used as experimental setup, which will be described within this chapter. The general setting of the proton-proton collider located at the CERN research center is the topic of section 4.1. The particle detection of the resulting collision events will take place in the ATLAS detector with its different specialized components (section 4.2). Section 4.3 addresses the possible leptoquark pair production in proton-proton collisions.

## 4.1 The Large Hadron Collider accelerator complex

The research center CERN (Conseil Européen pour la Recherche Nucléaire) was founded in 1954 near Geneva, Switzerland to become a major European joint venture on elementary particle physics. Currently 22 member states are participating in that large-scale project with the ambition to probe the essential constituents of nature and the fundamental forces acting between them. [12]

In the accelerator complex protons reach energies of 6.5 TeV by going through different accelerator stages and are brought to collisions at defined interaction sites in time intervals of 25 ns. Particle detectors then register signatures of the resulting collision events and the analysis of newly created particles gives insight to the nature of elementary particle physics.

Figure 4.1 shows the different acceleration stages. Starting from the injection, protons will gain a kinetic energy of 50 MeV in the linear accelerator LINAC2 and will be

**Figure 4.1:** Schematic of the CERN accelerator complex with its different stages and few experiments like ATLAS located at one crossing point for protons. [13]

further transferred to the Proton Synchrotron Booster (1.4 GeV), the Proton Synchrotron (25 GeV), the Super Proton Synchrotron (450 GeV) and finally to the LHC ring with its 26.7 km circumference. [12]

The LHC is designed as two-ring proton-proton collider. Conditions for a stable proton beam are diverse, including high vacua of  $10^{-10}$  mbar to  $10^{-11}$  mbar and temperatures of 1.9 K for the superconducting NbTi-magnets of the accelerator. [14]

Different experiments like ALICE[15], LHCb[16] are located at the LHC due to the variety of research questions. But the subject of interest in this work lies in the high luminosity experiment ATLAS, which is specialized for proton-proton collisions, like its counterpart CMS[17]. Main tasks of ATLAS are more precise measurements of the SM (see chapter 3.1), better understanding Quantum Chromo Dynamics (QCD) and search for supersymmetric models, and new physics, among others. With the LHC production of  $10^9$  inelastic events per second, up to 23 simultaneously events at dominating high QCD cross sections require a powerful detector that is capable of recognizing the characteristic signatures. These circumstances make up the demands for ATLAS, including fast electronic elements, high detector granularity, handling high particles fluxes and reducing overlapping events at a large acceptance and coverage region. [18]

## 4.2 The ATLAS detector at the LHC

One of the general purpose detector for proton-proton collisions is the ATLAS detector. This 25 m tall detector is located at one interaction point of the LHC where bunches, consisting of approximately  $10^{11}$  protons, collide at a rate of 40 MHz [18]. The number of particles encountered per time is given by [19]

$$\dot{N} = \mathcal{L}\sigma \quad (4.1)$$

with the cross section  $\sigma$  for the present event and the instantaneous luminosity  $\mathcal{L}$ . Given a measure for the number of collisions per unit time the instantaneous luminosity can be introduced and is often used as key parameter in collider physics [14].

$$\mathcal{L} = \frac{N_b n_b f_{\text{rev}} \gamma_r}{4\pi \epsilon_n \beta^*} F \quad (4.2)$$

Where  $N_b$  is the number of particles per bunch,  $n_b$  the number of bunches per beam,  $f_{\text{rev}}$  the rotational frequency,  $\gamma_r$  the Lorentz factor,  $\epsilon_n$  the normalized transverse beam emittance,  $\beta^*$  the betatron function at the collision point and  $F$  respects the geometric luminosity reduction factor due to the crossing angle at the collision point. The luminosity of ATLAS exceeded the design luminosity of  $\mathcal{L} = 2.05 \times 10^{34} \text{ cm}^{-2} \text{ s}^{-1}$  by a factor of 2.05 on the 2<sup>nd</sup> of November 2017, emphasizing the great success over the years [20].

The aspiration to be sensitive to the great variety of particles governed by the fundamental forces (see chapter 3.1) influenced the detector design accordingly. The layered structure reflects the fact that The basic structure of ATLAS is shown in figure 4.2 with its different sub-detector systems together with the convention for the used coordinate system. The nominal interaction point acts as origin of the coordinate system, where the  $z$ -axis follows the beam line counterclockwise. Perpendicular to the  $z$  axis lies the transverse  $x$ - $y$ -plane usually described through the azimuthal angle  $\phi$ . The positive  $x$ -axis points towards the center of the LHC. The cylindric symmetry of the detector suggests a cylindric coordinate system with the angle  $\theta$  starting from the beamline. [18] Since the polar angle is not a Lorentz invariant quantity, it is useful to describe the position in terms of rapidity [14]  $w = \frac{1}{2} \ln \frac{E+p_z c}{E-p_z c}$  in that highly relativistic regime. In the limit of large momenta, i.e.  $|\mathbf{p}|c \approx E$ , the rapidity coincides with the pseudorapidity formulated as [21]

$$\eta = -\ln \tan \frac{\theta}{2}. \quad (4.3)$$

This variable has only the polar angle as dependence and is therefore the adequate quantity in the context of collision experiments, where usually the angle  $\theta$  from the beamline is measured. [21]

**The magnet configuration** includes a superconducting solenoid with a field strength of 2 T surrounding the inner detector as well as three large superconducting toroid magnets composed in an eight-fold azimuthal symmetry around the calorimeter. The barrel toroid magnet delivers a field strength of 0.5 T and in the end-cap a field of 1 T is present. [18]

**The inner detector** is responsible for pattern recognition, momentum and vertex measurements and electrically charged particle identification which is achieved with a combination of semiconductor pixel and microstrip trackers (SCT). The Insertable B-Layer (IBL) is the innermost layer of the pixel detectors at a radius of 3.3 cm away from the beam line. Additional straw tube tracking detectors are sensitive to tran-

(a) The layered structure of the ATLAS Detector at the LHC with its sub-systems Inner Detector, Calorimeter, magnets and Muon Spectrometer [18].

(b) The global ATLAS coordinate system formulated in cylindric coordinates with the  $z$ -axis parallel to the beam line and the transverse plane defined through azimuthal angle  $\phi$  and pseudorapidity  $\eta$ . Based on [18].

**Figure 4.2:** Structure of the ATLAS detector and the used coordinate system.

sition radiation (TRT) in the outer part that are responsible for high vertex and momentum resolution. The  $R - \phi$  segmented pixel detectors are of size  $50 \times 400 \mu\text{m}^2$  and the SCTs with its 8 strip layers cover together a range of  $|\eta| < 2.5$ . Typically 36 hits per track are provided by the 4 mm straw tubes of the TRTs, which cover the range  $|\eta| \leq 2.0$ . [22][18]

Liquid argon electromagnetic sampling **calorimeters** with high granularity allow an excellent energy measurement for electrons and photons. It has a total thickness of more than 22 radiation lengths  $X_0$  in the barrel region ( $|\eta| < 1.475$ ) and more than  $24X_0$  in the end-cap region ( $1.375 < |\eta| < 3.2$ ). For hadronic energy measurements a scintillator-tile calorimeter covering  $|\eta| < 1.7$  is in operation. It is a sampling calorimeter and uses steel as absorber material and scintillating tiles as active material in conjunction with wavelength shifting fibres. Further LAr technology is used for hadronic particles in the outer pseudorapidity range up to  $|\eta| = 3.2$ . Here copper plates provide the absorber material. The forward calorimeters extend the coverage for hadronic and electromagnetic energy measurements to  $|\eta| = 4.9$  and are  $10X_0$  deep. [18]

The **muon system** is suited in the outer layer of ATLAS and provides as independent system resolution for high energy muon tracks with three layered precision chambers. This is possible because of the air-cored toroid magnet system including one barrel and two end-cap magnets generating strong bending power in a large volume and delivering a mostly perpendicular magnetic field regarding the muon trajectories. The bending power  $\int \vec{B} d\vec{l}$  along the track of the muon  $d\vec{l}$  reaches 1.5 T m to 5.5 T m in the range  $|\eta| < 1.4$  (barrel) and up to 7.5 T m (end-cap). The precision chambers are Monitored Drift Tubes (MDT) and in the larger pseudorapidity range Chathode Strip Chambers (CSC) which are multiwire proportional chambers. Due to the fact that the overall performance depends crucially on the alignment of the muon detectors with respect to each other and in respect to the Inner Detector, MDTs are equipped with a optical monitoring system with 1200 sensors. Resistive Plate Chambers (RPC) and Thin Gap Chambers (TGC) are the constituents of the muon trigger system. [18]

Due to technology and resource limitations the data recording rate has to be reduced from 40 MHz to 200 Hz. This poses high demands on an efficient **trigger system** which is organised in three levels. Level 1 uses only a subset of the total detector information making basic decisions to flag so called regions of interest, i.e. coordinate regions. Searches include patterns for high transverse momenta of muon tracks, electrons and photons as well as jets or large missing energy balances. The output rate after this first selection accounts for 75 kHz. The high level trigger 2 and 3 are responsible for selecting the level 1 triggerd regions at full granularity and

precision. The level 3 event filter is the final stage and achieves data reduction down to the final data-taking rate of 200 Hz, writing events of the size of approximately 1.3 MB to the disks. The event filter's selection criteria are implemented using offline analysis procedures. [18]

## **4.3 Leptoquark pair production in proton-proton collisions**

# Turning detector signatures into physical objects

## 5.1 b-tagging at ATLAS – identifying b-jets

The third generation quarks, i.e. top (t) and bottom (b), play a crucial role in the Standard Model and its various extension possibilities like the Leptoquark Model due to their large masses [23]. Therefore, it is essential to identify hadrons containing b quarks and separating them from light-flavour quarks at hadron collider detectors like ATLAS. This task is commonly referred as b-tagging and can be seen as a classification problem with the goal to assign right jet flavours. To that end the particle tracks in the Inner Detector and the jet reconstruction of clusters in the electromagnetic and hadronic calorimeter are discriminating objects. [24]

**Figure 5.1:** Signature of a b-jet with the primary and secondary vertex created relevant for b-tagging.  $d_0$  is the impact parameter. [23]

The long lifetime of B hadrons in the order of 1.6 ps allow them to travel a few millimeters in the detector. The subsequent decay of those heavy particles within

a secondary vertex produce tracks with comparably large impact parameter  $d_0$  that is the shortest distance of the particle track from the primary vertex (see figure 5.1). This signature and the deduced impact parameter significance  $S(d_0) = \frac{d_0}{\sigma(d_0)}$ , where  $\sigma(d_0)$  is the uncertainty of the impact parameter, are used by the *b*-tagging algorithms including five low-level and two high-level taggers. [23] The *b*-tagging algorithms rely on multivariate combinations of the information and process them to calculate a discriminant value for each jet. Thresholds on these values are then defining the working point to provide efficient identification of *b*-jets. For better information processing of the combinations of large input parameters neural network classes are used. [25] One example for such a trained network is the MV2 tagger which uses 24 input variables of the low-level taggers together with kinematic properties\*. [24]

---

\*For further details on MV2 see [26]

## **Data analysis**

---

**6.1 Current status in the search for scalar leptoquarks**

**6.2 Starting point and research question for the analysis**

**6.3 Used data and Monte Carlo samples**

**6.4 Physical object selection**

**6.5 Event selection**

---

## Results

---

---

## Outlook

---

---

# List of Figures

---

3.1	Overview of the Standard Model. . . . .	13
4.1	Schematic of the CERN accelerator complex. . . . .	16
4.2	Structure of the ATLAS detector and the used coordinate system. . . .	19
5.1	Tracks in a b-jet. . . . .	22

---

# List of Tables

---

1.1	Event yield for the $t\bar{t}$ , $t\bar{t}H$ and the LQ samples. . . . .	5
1.2	Efficiencies for the $t\bar{t}$ and the $t\bar{t}H$ sample. . . . .	5
1.3	Ratios for the $t\bar{t}$ and the $t\bar{t}H$ sample. . . . .	6
1.4	Event yield for the $t\bar{t}$ and the $t\bar{t}H$ sample. . . . .	6
3.1	Lie symmetry groups of the Standard Model. . . . .	10
3.2	Overview of elementary particles with some selected properties. . . .	12
