# Experimental setup for the search of scalar leptoquarks

---

For the search of scalar leptoquarks the ATLAS detector at the Large Hadron Collider (LHC) is used as experimental setup which will be described within this chapter. In section 3.1 the general setting of the proton-proton collider located at the CERN research center is the subject of interest. The particle detection of the resulting collision events will take place in the ATLAS detector with its different specialized components (section 3.2). Section 3.3 addresses the leptoquark pair production in proton-proton collisions.

## 3.1 The Large Hadron Collider accelerator complex

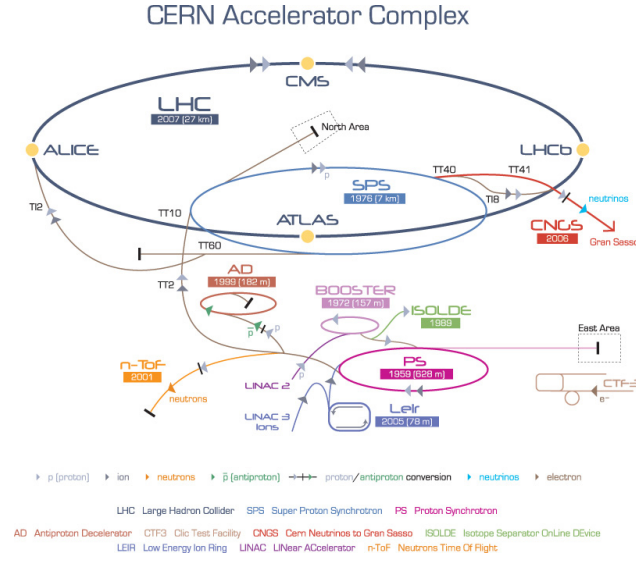

The research center CERN (Conseil Européen pour la Recherche Nucléaire) was founded in 1954 near Geneva, Switzerland to become a major European joint venture on elementary particle physics. In the mean time 22 member states are participating in that large-scale project with the ambition to probe the essential constituents of nature and the fundamental forces acting between them. [?]

In the huge accelerator complex protons reach through different stages energies of 6.5 TeV and will be brought to collisions at defined interaction sites in time intervals of 25 ns. Particle detectors then register signatures of the resulting collision events and the analysis of new created particles gives insight to the nature of elementary particle physics.

Figure 3.1 shows the different acceleration stages. Starting from the injection protons will gain as much energy as 50 MeV in the linear accelerator LINAC2 and will

**Figure 3.1:** Schematic of the CERN accelerator complex with its different stages and few experiments like ATLAS located at a crossing point for protons. [?]

be further transferred to the Proton Synchrotron Booster (1.4 GeV), the Proton Synchrotron (25 GeV), the Super Proton Synchrotron (450 GeV) and finally to the LHC ring with its 26.7 km circumference. [?]

The LHC is designed as two-ring proton-proton collider. Conditions for a stable proton beam are diversely including high vacua of  $10^{-10}$  mbar to  $10^{-11}$  mbar and temperatures of 1.9 K for the superconducting NbTi-magnets of the accelerator. [?]

Different more experiments like ALICE[?], LHCb[?] are located at CERN due to the variety of research questions. But the subject of interest in this work lies in the high luminosity experiment ATLAS specialized for proton-proton collisions like its counterpart CMS[?].

## 3.2 The ATLAS detector at the LHC

One of the general purpose detector for proton-proton collisions is the ATLAS detector. This 25 m tall detector is located at one interaction point of the LHC where bunches, consisting of approximately  $10^{11}$  protons, collide at a rate of 40 MHz [?]. The number of particles encountered per time is given by [?]

$$\dot{N} = \mathcal{L}\sigma \quad (3.1)$$

with the cross section  $\sigma$  for the present event and the instant luminosity  $\mathcal{L}$ . Given a measure for the number of collisions per unit time the instant luminosity can be introduced and is often used as key parameter in collider physics [?].

$$\mathcal{L} = \quad (3.2)$$

The design luminosity for ATLAS was exceeded with  $\mathcal{L} = 2.05 \times 10^{34} \text{ cm}^{-2} \text{ s}^{-1}$  for 2.05 times on the 2<sup>nd</sup> of November 2017 emphasizing the great success over the years [?].

The basic structure is shown in figure 3.2 with its different sub-detector systems.

**Figure 3.2:** The layered structure of the ATLAS detector at the LHC and the used coordinate system. [?]
